## **Mega Clover Plus**

### **Product Instructions**

1. Mega Clover Plus can be planted in the spring or in late summer. Do not plant during periods of extended drought, young clover is easily damaged if it germinates and then dries out.
2. Prepare plot by killing off existing vegetation with Roundup (glyphosate) according to label instructions. The more weeds you kill before planting, the fewer weed problems you will have in the plot.
3. Test the soil in the plot. **Ideal Ph for Mega Clover Plus is 6.5.** Apply lime and fertilizer according to recommendation from the testing service.
4. Disk the plot and then if necessary use a drag to level and smooth the soil.
5. **Spread or plant Mega Clover Plus Mix at a rate of 11 pounds per acre. Mega Clover Plus seeds are extremely small!** If you are not familiar with how your seeder works with fine seed like clover, we suggest you do a measured test area first to be sure your seeder is set correctly and spreading seed at the correct rate.

**If broadcasting, it is often easier and more accurate to set the seeder at half of the recommended seeding rate ( $\frac{1}{2}$  seeding rate = 5.5 pounds per acre for Mega Clover Plus) and then go over the plot twice to ensure even seeding.**

6. **Mega Clover Plus can be damaged and its growth held back by excessive deer grazing pressure while the plants are establishing. We recommend adding a “nurse crop” of oats or rye grain to protect the clover and ease deer grazing pressure.**

**In most areas, oats seeded at a rate of 50-100 pounds per acre are an excellent nurse crop and help the clover to grow faster by providing a fast growing, highly-desirable plant for the deer to eat while the clover establishes.**

7. Compact the entire plot with a cultipacker (preferred) or with a flat roller to increase seed to soil contact. Do NOT disk or drag the plot after planting!
8. Germination depends largely on rainfall and temperatures. It is always better to plant on moist ground or right before a rainfall if possible.
